#### Abstract

We propose an efficient variant of a primal Discontinuous Galerkin method with interior penalty for the second order elliptic equations on very general meshes (polytopes with eventually curved boundaries). Efficiency, especially when higher order polynomials are used, is achieved by static condensation, i.e. a local elimination of certain degrees of freedom cell by cell. This alters the original method in a way that preserves the optimal error estimates. Numerical experiments confirm that the solutions produced by the new method are indeed very close to that produced by the classical one.

Keywords Discontinuous Galerkin • static condensation • polyhedral (polygonal) meshes

## 1 Introduction

The recent years have seen the emergence (or the revival) of several numerical methods capable to solve approximately elliptic partial differential equations using general polygonal/polyhedral meshes. This is witnessed for example by the book [4]. The methods reviewed in this book (if we restrict our attention only to finite element type methods using piecewise polynomial approximation spaces in one form or another) include interior penalty discontinuous Galerkin (DG) methods [6, 2], hybridizable discontinuous Galerkin (HDG) methods ([8], introduced in [10]), the Virtual Element (VE) method ([21], introduced in [20,5]), the Hybrid High-Order (HHO) method ([14], introduced in [12|,13]). One can add to this list the weak Galerkin finite element [22], which is similar to HDG. The relations between HHO and HDG methods were exhibited in [9].

[^0]Among the above, the primal interior penalty DG methods are the most classical. In the symmetric form, also referred to as SIP - symmetric interior penalty, this method dates back to [24,3] and is now presented and thoroughly studied in several monographs, for example [19, 11]. It is well suited to the discretization on very general meshes because its approximation space is populated by polynomials of degree, say $\leq k$, on each mesh cell without any constraints linking the polynomials on two adjacent cells. It leaves thus a lot of freedom on the choice of the mesh cells which can be not only polytopes but also virtually any geometrical shapes. It is generally admitted however that the SIP method is too expensive especially when higher order polynomials are employed. Indeed, its cost, i.e. the dimension of the approximation space, is the product of the number of mesh cells and the dimension of the space of polynomials of degree $\leq k$. The cost on a given mesh is thus proportional to $k^{2}$ in 2D (resp. $k^{3}$ in 3D). This should be contrasted with the cost of HDG or HHO methods which is proportional to $k$ in 2D (resp. $k^{2}$ in 3D).

The goal of the present article is to modify the SIP method so that its cost is reduced to that of HDG or HHO methods. In doing so, we inspire ourselves from the static condensation procedure for the standard continuous Galerkin (CG) finite element methods. It is indeed well known that the dimension of the approximation space in CG is proportional to $k^{2}$ in 2D on a given mesh, but the degrees of freedom interior to each mesh cell can be locally eliminated which leaves a global problem of the size proportional to $k$ (these numbers are changed to, respectively, $k^{3}$ and $k^{2}$ in 3D). Although the notion of interior degrees of freedom does not make sense in the DG context, we shall be able to select, on each mesh cell, a subspace of the approximating polynomials that can be used to construct a local approximation through the solution of a local problem. The remaining degrees of freedom will then be used in a global problem. We shall thus achieve a significant reduction of the global problem size in the DG SIP-like method, similarly to that achieved in CG by static condensation. The resulting DG method, which can be refereed to as scSIP (static condensation SIP), will not produce exactly the same approximation as the original SIP method. We shall prove however that these two solutions satisfy the same optimal a priori error bounds in $H^{1}$ and $L^{2}$ norms. Moreover, they turn out to be very close to each other in our numerical experiments.

We treat here only the diffusion equation with variable, but sufficiently smooth, coefficients. The extension to other problems, such as convection-reaction-diffusion, linear elasticity, Stokes, as well as to other DG variants (IIP, NIP) seems relatively straight-forward. Our assumptions on the mesh allow for cells of general shape, not necessarily the polytopes.

The article is organized as follows: in the next section, we present the idea of our method starting by the description of the governing equations. We the recall the static condensation for the classical CG FEM. Our variants of DG FEM (SIP and scSIP) are first introduced in Subsection 22. The convergence proofs are in Section 3. They are done assuming some properties of the discontinuous FE spaces and the underlying mesh. In Section 4, we give an example of the hypotheses on the mesh under which the necessary properties of the FE spaces can be established. Finally, some implementation details and numerical illustrations are presented in Section 5

## 2 Description of the problem and static condensation for FEM (CG and DG cases)

We consider the second-order elliptic problem

$$
\begin{equation*}
\mathscr{L} u=f \text { in } \Omega, \quad u=g \text { on } \partial \Omega \tag{1}
\end{equation*}
$$

where $\Omega \subset \mathbb{R}^{d}, d=2$ or 3 , is a bounded Lipschitz domain, $f \in L^{2}(\Omega)$ and $g \in$ $H^{1 / 2}(\partial \Omega)$ are given functions. The differential operator $\mathscr{L}$ is defined by

$$
\mathscr{L} u=-\partial_{i}\left(A_{i j}(x) \partial_{j} u\right)
$$

with $\partial_{i}$ denoting the partial derivative in the direction $x_{i}, i=1, \ldots, d$ and assuming the summation over $i, j$. The coefficients $A_{i j}$ are supposed to form a positive definite matrix $A=A(x)$ for any $x \in \Omega$ which is sufficiently smooth with respect to $x$ so that

$$
\begin{equation*}
\alpha|\xi|^{2} \leq \xi^{T} A(x) \xi \leq \beta|\xi|^{2}, \quad \forall \xi \in \mathbb{R}^{d}, x \in \Omega \tag{2}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|\nabla A_{i j}(x)\right| \leq M, \quad \forall x \in \Omega, i, j=1, \ldots, d \tag{3}
\end{equation*}
$$

with some constants $\beta \geq \alpha>0, M>0$.

### 2.1 Static condensation for CG FEM

To present our idea, we start by recalling the idea of static condensation, going back to [17], as applied to the usual CG finite element method for problem (1). Let us assume for the moment (in this subsection only) that $\Omega$ is a polygon (polyhedron) and introduce a conforming mesh $\mathscr{T}_{h}$ on $\Omega$ consisting of triangles (tetrahedrons). Assuming for simplicity $g=0$, the usual continuous $\mathbb{P}_{k}$ finite element discretization of (1) is then written: find $u_{h} \in W_{h}$ such that

$$
\begin{equation*}
a\left(u_{h}, v_{h}\right):=\int_{\Omega} A \nabla u_{h} \cdot \nabla v_{h}=\int_{\Omega} f v_{h}, \quad \forall v_{h} \in W_{h} \tag{4}
\end{equation*}
$$

where $W_{h}$ is the space of continuous piecewise polynomial functions (polynomials of degree $\leq k$ on each mesh cell $T \in \mathscr{T}_{h}$ for some $k \geq 1$ ) vanishing on $\partial \Omega$. The size of this problem, i.e. the dimension of $W_{h}$, is of order $k^{2}$ on a given mesh in 2D (resp. $k^{3}$ in 3D). To reduce this cost, one can decompose the space $W_{h}$ as follows

$$
W_{h}=W_{h}^{l o c} \oplus W_{h}^{\prime}
$$

where the subspace $W_{h}^{l o c}$ consists of functions of $W_{h}$ that vanish on the boundaries of all the mesh cells $T \in \mathscr{T}_{h}$, and $W_{h}^{\prime}$ is the complement of $W_{h}^{\text {loc }}$, orthogonal with respect to the bilinear form $a$. Decomposing $u_{h}=u_{h}^{l o c}+u_{h}^{\prime}$ with $u_{h}^{l o c} \in W_{h}^{l o c}$ and $u_{h}^{\prime} \in W_{h}^{\prime}$ we see that (4) is split into two independent problems

$$
\begin{align*}
u_{h}^{l o c} \in W_{h}^{l o c}: & a\left(u_{h}^{l o c}, v_{h}^{l o c}\right)=\int_{\Omega} f v_{h}^{l o c}, \quad \forall v_{h}^{l o c} \in W_{h}^{l o c}  \tag{5}\\
u_{h}^{\prime} \in W_{h}^{\prime}: & a\left(u_{h}^{\prime}, v_{h}^{\prime}\right)=\int_{\Omega} f v_{h}^{\prime}, \quad \forall v_{h}^{\prime} \in W_{h}^{\prime} \tag{6}
\end{align*}
$$

The first problem above is further split into a collection of mutually independent problems on every mesh cell $T \in \mathscr{T}_{h}$ :

$$
\begin{equation*}
\text { Find } u_{h}^{l o c, T} \text { such that } \int_{T} A \nabla u_{h}^{l o c, T} \cdot \nabla v_{h}^{l o c, T}=\int_{\Omega} f v_{h}^{l o c, T}, \quad \forall v_{h}^{l o c, T} \in W_{h}^{l o c, T} \tag{7}
\end{equation*}
$$

where $W_{h}^{l o c, T}$ is the restriction of $W_{h}^{l o c}$ on $T$, i.e. the set of all polynomials of degree $\leq k$ vanishing on $\partial T$. The cost of solution of these local problems is negligible and we thus get very cheaply $\left.u_{h}^{l o c}\right|_{T}=u_{h}^{l o c, T}$. Note also that Problem $\sqrt{77}$ can be recast as

$$
\begin{equation*}
\pi_{T} \mathscr{L}\left(\left.u_{h}^{l o c}\right|_{T}\right)=\pi_{T} f, \quad \forall T \in \mathscr{T}_{h} \tag{8}
\end{equation*}
$$

where $\pi_{T}$ is the projection to $W_{h}^{l o c, T}$, orthogonal in $L^{2}(T)$.
On the other hand, Problem (6) remains global but its size is only proportional to $k$ in 2D (resp. $k^{2}$ in 3D) which is much smaller than that of the original problem (4). Indeed, the degrees of freedom are associated to the standard interpolation points of $\mathbb{P}^{k}$ finite elements on the edges of the mesh. Note also that a basis for $W_{h}^{\prime}$ can be constructed solving cheap local problems of the type

$$
\begin{equation*}
\pi_{T} \mathscr{L}\left(\left.v_{h}^{\prime}\right|_{T}\right)=0, \quad \forall T \in \mathscr{T}_{h} \tag{9}
\end{equation*}
$$

with appropriate boundary conditions on $\partial T$ insuring the continuity of functions in $W_{h}^{\prime}$.

### 2.2 DG FEM: SIP and scSIP methods

We turn now to the main subject of this paper: the DG methods. We now let $\Omega$ be a bounded domain of general shape, and $\mathscr{T}_{h}$ be a splitting of $\Omega$ into a collection of non-overlapping subdomains (again of general shape, the precise definitions and assumptions on the mesh will be given Sections 3 and (4). Let $V_{h}$ denote the space of discontinuous piecewise polynomial functions of degree $\leq k$ on each mesh cell $T \in \mathscr{T}_{h}$ for some $k \geq 2 \cdot{ }^{1}$

$$
\begin{equation*}
V_{h}=\left\{v \in L^{2}(\Omega):\left.v\right|_{T} \in \mathbb{P}_{k}(T), \forall T \in \mathscr{T}_{h}\right\} \tag{10}
\end{equation*}
$$

The SIP (symmetric interior penalty) method is then written as: find $u_{h} \in V_{h}$ such that

$$
\begin{equation*}
a_{h}\left(u_{h}, v_{h}\right)=L_{h}\left(v_{h}\right), \quad \forall v_{h} \in V_{h} \tag{11}
\end{equation*}
$$

with the bilinear form $a_{h}$ and the linear form $L_{h}$ defined by

$$
\begin{align*}
& a_{h}(u, v)=\sum_{T \in \mathscr{F}_{h}} \int_{T} A \nabla u \cdot \nabla v-\sum_{E \in \mathscr{C}_{h}} \int_{E}(\{A \nabla u \cdot n\}[v]+\{A \nabla v \cdot n\}[u]) \\
&+\sum_{E \in \mathscr{C}_{h}} \frac{\gamma}{h_{E}} \int_{E}[u][v] \tag{12}
\end{align*}
$$

[^1]and
\[

$$
\begin{equation*}
L_{h}(v)=\sum_{T \in \mathscr{T}_{h}} \int_{T} f v+\sum_{E \in \mathscr{E}_{h}^{b}} \int_{E} g\left(\frac{\gamma}{h_{E}} v-A \nabla v \cdot n\right) \tag{13}
\end{equation*}
$$

\]

where $\mathscr{E}_{h}$ is the set of all the edges/faces of the mesh, $\mathscr{E}_{h} \subset \mathscr{E}_{h}$ regroups the edges/faces on the boundary $\partial \Omega, n,[\cdot]$ and $\{\cdot\}$ denote the unit normal, the jump and the mean over $E \in \mathscr{E}_{h}$. More precisely, for any internal facet $E$ shared by two mesh cells $T_{1}^{E}$ and $T_{2}^{E}$, we choose $n$ as the unit vector, normal to $E$ and looking from $T_{1}^{E}$ to $T_{2}^{E}$. We then define for any function $v$ which is $H^{1}$ on both $T_{1}^{E}$ and $T_{2}^{E}$ but discontinuous across $E$

$$
\left.[v]\right|_{E}:=\left.v\right|_{T_{1}^{E}}-\left.v\right|_{T_{2}^{E}},\left.\quad\{A \nabla v \cdot n\}\right|_{E}:=\frac{1}{2} A\left(\left.\nabla v\right|_{T_{1}^{E}}+\left.\nabla v\right|_{T_{2}^{E}}\right) \cdot n
$$

On a boundary edge $E \in \mathscr{E}_{h}^{b}, n$ is the unit normal looking outward $\Omega$ and $[v]=v$, $\{A \nabla v \cdot n\}=A \nabla v \cdot n$. The parameter $h_{E}$ in (12)-13) is the local length scale of the mesh near the facet $E$ which will be properly defined in Lemma $\left.1\right|^{2}$ Finally, $\gamma$ is the interior penalty parameter which should be chosen sufficiently big.

Unlike the case of continuous finite elements, Problem (11) does not allow directly for a static condensation. However, we can construct a modification of 11) that mimics the characterization of local and global components of the solution by the projectors on local polynomial spaces $(8)-(9)$. These spaces are now defined simply as

$$
V_{h}^{l o c, T}=\mathbb{P}^{k-2}(T)
$$

We also let $\pi_{T, k-2}$ to be the projection to $V_{h}^{l o c, T}$, orthogonal in $L^{2}(T)$, and propose the following scheme:

- Compute $u_{h}^{l o c} \in V_{h}$ by solving

$$
\begin{equation*}
\pi_{T, k-2} \mathscr{L}\left(\left.u_{h}^{l o c}\right|_{T}\right)=\pi_{T, k-2} f, \quad \forall T \in \mathscr{T}_{h} \tag{14}
\end{equation*}
$$

i.e. find $\left.u_{h}^{l o c}\right|_{T} \in \mathbb{P}^{k}(T)$ on all mesh cells $T \in \mathscr{T}_{h}$ such that

$$
\int_{T} \mathscr{L}\left(\left.u_{h}^{l o c}\right|_{T}\right) q_{T}=\int_{T} f q_{T}, \quad \forall q_{T} \in \mathbb{P}^{k-2}(T)
$$

- Define the subspace of $V_{h}$

$$
\begin{equation*}
V_{h}^{\prime}=\left\{v_{h}^{\prime} \in V_{h}: \pi_{T, k-2} \mathscr{L}\left(\left.v_{h}^{\prime}\right|_{T}\right)=0, \quad \forall T \in \mathscr{T}_{h}\right\} \tag{15}
\end{equation*}
$$

i.e. the subspace of functions $v_{h}^{\prime} \in V_{h}$ such that

$$
\begin{equation*}
\int_{T} \mathscr{L}\left(\left.v_{h}^{\prime}\right|_{T}\right) q_{T}=0, \quad \forall q_{T} \in \mathbb{P}^{k-2}(T) \tag{16}
\end{equation*}
$$

on all mesh cells $T \in \mathscr{T}_{h}$.

[^2]- Compute $u_{h}^{\prime} \in V_{h}^{\prime}$ such that

$$
\begin{equation*}
a_{h}\left(u_{h}^{\prime}, v_{h}^{\prime}\right)=L_{h}\left(v_{h}^{\prime}\right)-a_{h}\left(u_{h}^{l o c}, v_{h}^{\prime}\right), \quad \forall v_{h}^{\prime} \in V_{h}^{\prime} \tag{17}
\end{equation*}
$$

- Set

$$
\begin{equation*}
u_{h}=u_{h}^{l o c}+u_{h}^{\prime} . \tag{18}
\end{equation*}
$$

We shall show that the local problem (14) admits an infinity of solutions. We can choose any of these solutions on each mesh cell to form $u_{h}^{\text {loc }}$. Nevertheless, the final result $u_{h}$ given by 18 is unique, cf. Lemma 3

Note that the dimension of the "global" space $V_{h}^{\prime}$ on a given mesh is of order $k$ in 2D ( $k^{2}$ in 3D) so that global problem 17) is much cheaper than for large $k$. We have thus asymptotically the same costs for the global problems as for CG FEM with static condensation. There is though a fundamental difference between static condensation approaches in CG and DG cases from the implementation point of view: the basis functions for the global space $W_{h}^{\prime}$ in the CG case are known a priori, whereas those for the space $V_{h}^{\prime}$ in the DG case should be constructed as solutions to local problems (16), cf. the discussion of the implementation issues in Subsection 5.1. Note however that one can get rid of problems (16) in the special case of a constant coefficient matrix $A$ in (1), cf. Remark 1 Indeed, 16) is reduced in this case to $\mathscr{L}\left(\left.v_{h}^{\prime}\right|_{T}\right)=A_{i j} \partial_{i} \partial_{j}\left(\left.v_{h}^{\prime}\right|_{T}\right)=0$ on any cell $T \in \mathscr{T}_{h}$. The structure of $V_{h}^{\prime}$ does not thus vary from one cell to another and a basis for $V_{h}^{\prime}$ can be chosen a priori on all the cells.

The local projection step $\sqrt{14}$ is not necessarily consistent with the original formulation (11) so that the solution $u_{h}$ given by (14)-(18) is different from that of (11). We shall prove however that SIP and scSIP approximations satisfy the same a priori error bounds. Moreover, they turn out to be very close to each other in numerical experiments.

## 3 Well posedness of SIP and scSIP methods and a priori error estimates

Let us now be more precise about the hypotheses on the mesh. Recall that $\Omega \subset$ $\mathbb{R}^{d}, d=2$ or 3 , is a Lipschitz bounded domain and $\mathscr{T}_{h}$ is a general (not necessarily polygonal or polyhedral) mesh on $\Omega$. We mean by this that $\mathscr{T}_{h}$ is a decomposition of $\Omega$ into mutually disjoint cells $\bar{\Omega}=\cup_{T \in \mathscr{T}_{h}} \bar{T}$ so that each cell $T$ is a Lipschitz subdomain of $\Omega$ and for every $T_{1}, T_{2} \in \mathscr{T}_{h}$ we have either $T_{1}=T_{2}$ or $T_{1} \cap T_{2}=\varnothing$ (the cells $T_{1} \in \mathscr{T}_{h}$ are treated here as open sets). We also introduce the sets of internal and boundary edges/faces as respectively

$$
\begin{aligned}
\mathscr{E}_{h}^{i} & =\left\{E=\bar{T}_{1} \cap \bar{T}_{2} \text { for some } T_{1}, T_{2} \in \mathscr{T}_{h}\right\} \\
\mathscr{E}_{h}^{b} & =\left\{E=\bar{T} \cap \partial \Omega \text { for some } T \in \mathscr{T}_{h}\right\}
\end{aligned}
$$

and denote by $\mathscr{E}_{h}:=\mathscr{E}_{h}^{i} \cap \mathscr{E}_{h}^{b}$ the union of all the edges/faces.
Let $B_{T}$, for any $T \in \mathscr{T}_{h}$, denote the smallest ball containing $T$, and $B_{T}^{i n}$ denote the largest ball inscribed in $T$. Set $h_{T}=\operatorname{diam}(T)$ and $h=\max _{T \in \mathscr{T}_{h}} h_{T}$. From now on, we assume that mesh $\mathscr{T}_{h}$ is

- Shape regular: there is a mesh-independent parameter $\rho_{1}>1$ such that, for all $T \in \mathscr{T}_{h}$,

$$
\begin{equation*}
R_{T} \leq \rho_{1} r_{T} \tag{19}
\end{equation*}
$$

where $r_{T}$ is the radius of $B_{T}^{i n}$ and $R_{T}$ is the radius of $B_{T}$. This also implies $h_{T} \leq$ $2 \rho_{1} r_{T}$ and $R_{T} \leq \rho_{1} h_{T}$.

Choose an integer $k \geq 2$ and recall the discontinuous FE space 10). We assume that $V_{h}$ has two following properties (and we shall prove in Section4 that these properties hold under some additional assumptions on the mesh):

- Optimal interpolation: there exists an operator $I_{h}: H^{k+1}(\Omega) \rightarrow V_{h}$ such that for any $v \in H^{k+1}(\Omega)$

$$
\begin{align*}
& \left(\sum _ { T \in \mathscr { T } _ { h } } \left(\left|v-I_{h} v\right|_{H^{1}(T)}^{2}+\frac{1}{h_{T}^{2}}\left\|v-I_{h} v\right\|_{L^{2}(T)}^{2}+h_{T}^{2}\left|v-I_{h} v\right|_{H^{2}(T)}^{2}\right.\right.  \tag{20}\\
& \left.\left.\quad+h_{T}\left\|\nabla v-\nabla I_{h} v\right\|_{L^{2}(\partial T)}^{2}+\frac{1}{h_{T}}\left\|v-I_{h} v\right\|_{L^{2}(\partial T)}^{2}\right)\right)^{\frac{1}{2}} \leq C\left(\sum_{T \in \mathscr{T}_{h}} h_{T}^{2 k}|v|_{H^{k+1}(T)}\right)^{\frac{1}{2}}
\end{align*}
$$

- Inverse inequalities: for any $v_{h} \in V_{h}$ and any $T \in \mathscr{T}_{h}$

$$
\begin{equation*}
\left\|v_{h}\right\|_{L^{2}(\partial T)} \leq \frac{C}{\sqrt{h_{T}}}\left\|v_{h}\right\|_{L^{2}(T)} \quad\left\|\nabla v_{h}\right\|_{L^{2}(\partial T)} \leq \frac{C}{\sqrt{h_{T}}}\left\|\nabla v_{h}\right\|_{L^{2}(T)} \tag{21}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|v_{h}\right|_{H^{2}(T)} \leq \frac{C}{h_{T}}\left|v_{h}\right|_{H^{1}(T)} \tag{22}
\end{equation*}
$$

We can now study the well posedness and establish optimal a priori error estimates for the classical SIP method (11).

Lemma 1 Under the above assumptions on the mesh and on $V_{h}$, setting

$$
\begin{array}{ll}
h_{E}=2\left(\frac{1}{h_{T_{1}}}+\frac{1}{h_{T_{2}}}\right)^{-1} & \text { for any } E \in \mathscr{E}_{h}^{i} \text { with } E=\partial T_{1} \cap \partial T_{2},  \tag{23}\\
h_{E}=h_{T} & \\
\text { for any } E \in \mathscr{E}_{h}^{b} \text { with } E=\partial T \cap \partial \Omega,
\end{array}
$$

and choosing $\gamma$ large enough, $\gamma \geq \gamma_{0}$, the bilinear form $a_{h}$ defined by (12) is coercive, i.e.

$$
\begin{equation*}
a_{h}\left(v_{h}, v_{h}\right) \geq c\| \| v_{h} \|^{2}, \quad \forall v_{h} \in V_{h} \tag{24}
\end{equation*}
$$

with some $c>0$ and the triple norm defined by

$$
\begin{equation*}
\|v\| \|^{2}=\sum_{T \in \mathscr{T}_{h}}\left(|v|_{H^{1}(T)}^{2}+\frac{1}{h_{T}}\|[v]\|_{L^{2}(\partial T)}^{2}\right) \tag{25}
\end{equation*}
$$

The constants $c, \gamma_{0}$ depend only on the parameters in the assumptions on the mesh and on $V_{h}$, as well as on $\alpha, \beta$ in (2).

We skip the proof of this well known result. We stress however that our definitions of the length scale $h_{E}$ and of the triple norm (25) may be slightly different from those available in the literature. In particular, we avoid to use the diameter of a facet $E$ (or any other geometrical information on $E$ ) to define $h_{E}$. This choice enables us to establish straightforwardly the coercivity of $a_{h}$ with respect to the triple norm, which does not see the separate mesh facets either (only the whole boundaries of the mesh cells are present there). More elaborate choices for the interior penalty parameters are proposed in [6].

Lemma 1 implies that problem (11) of the SIP method is well posed. Moreover, we have the following error estimate, the proof of which is also skipped (actually, it goes along the same lines as that of our forthcoming Theorem(2).

Theorem 1 Assume that the solution $u$ to $\sqrt{1]}$ is in $H^{k+1}(\Omega)$. Under the assumptions of Lemma 1 there exists the unique solution $u_{h}$ to (11) and it satisfies

$$
\left|u-u_{h}\right|_{H^{1}\left(\mathscr{T}_{h}\right)} \leq C h^{k}|u|_{H^{k+1}(\Omega)}
$$

where $H^{1}\left(\mathscr{T}_{h}\right)$ is the broken $H^{1}$ space on the mesh $\mathscr{T}_{h}$ and $|\cdot|_{H^{1}\left(\mathscr{T}_{h}\right)}:=\left(\sum_{T \in \mathscr{T}_{h}}|\cdot|_{H^{1}(T)}^{2}\right)^{\frac{1}{2}}$. If, moreover, the elliptic regularity property holds for (7), then

$$
\left\|u-u_{h}\right\|_{L^{2}(\Omega)} \leq C|u|_{H^{k+1}(\Omega)} h^{k+1}
$$

We turn now to the study of the scSIP method $(14)-(17)$ and start by the following technical lemma.

Lemma 2 There exists $h_{0}>0$ such that for all $T \in \mathscr{T}_{h}$ with $h_{T} \leq h_{0}$ and for all $q_{T} \in \mathbb{P}_{k-2}(T)$ one can find $u_{T} \in \mathbb{P}_{k}(T)$ such that

$$
\begin{equation*}
\int_{T} q_{T}\left(\mathscr{L} u_{T}\right) \geq \frac{1}{2}\left\|q_{T}\right\|_{L^{2}(T)}^{2} \tag{26}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|u_{T}\right|_{H^{1}(T)}^{2}+\frac{1}{h_{T}}\left\|u_{T}\right\|_{L^{2}(\partial T)}^{2} \leq C h_{T}^{2}\left\|q_{T}\right\|_{L^{2}(T)}^{2} \tag{27}
\end{equation*}
$$

The constants $h_{0}$ and $C$ depend only on the regularity of the mesh and on $\alpha, \beta$ and $M$ in (2) and (3). One can put $h_{0}=+\infty$ if the coefficient matrix $A$ is constant on $T$.

Proof Let $\chi_{T}$ be the polynomial of degree 2 vanishing on $\partial B_{T}^{i n}$, i.e.

$$
\chi_{T}(x)=\left(\sum_{i=1}^{d}\left(x_{i}-x_{i}^{0}\right)^{2}-r_{T}^{2}\right)
$$

where $x^{0}=\left(x_{1}^{0}, \ldots, x_{d}^{0}\right)$ is the center of $B_{T}^{i n}$ and $r_{T}$ is its radius. Set $A_{i j}^{0}=A_{i j}\left(x^{0}\right)$ and $\mathscr{L}^{0}=-\partial_{i} A_{i j}^{0} \partial_{j}$. Consider the linear map

$$
Q: \mathbb{P}_{k-2}(T) \rightarrow \mathbb{P}_{k-2}(T)
$$

defined by

$$
Q(v)=\mathscr{L}^{0}\left(\chi_{T} v\right)
$$

The kernel of $Q$ is $\{0\}$. Indeed, if $Q(v)=0$ then $w:=\chi_{T} v$ is the solution to

$$
\mathscr{L}^{0} w=0 \text { in } B_{T}^{i n}, \quad w=0 \text { on } \partial B_{T}^{i n}
$$

so that $w=0$ as a solution to an elliptic problem with vanishing right-hand side and boundary conditions. Since $Q$ is a linear map on the finite dimensional space $\mathbb{P}_{k-2}(T)$, this means that $Q$ is one-to-one.

Take any $q_{T} \in \mathbb{P}_{k-2}(T)$ and let $u_{T}=\chi_{T} v_{T}$ with $v_{T} \in \mathbb{P}_{k-2}(T)$ such that $Q\left(v_{T}\right)=$ $q_{T}$. We have thus constructed $u_{T} \in \mathbb{P}_{k}(T)$ such that $\mathscr{L}^{0} u_{T}=q_{T}$. This immediately proves $\sqrt{26}$ in the case of an operator $\mathscr{L}=\mathscr{L}^{0}$ with constant coefficients. Moreover, by scaling,

$$
\begin{equation*}
\left|u_{T}\right|_{W^{2, \infty}\left(B_{T}\right)}+\frac{1}{h_{T}}\left|u_{T}\right|_{W^{1, \infty}\left(B_{T}\right)}+\frac{1}{h_{T}^{2}}\left\|u_{T}\right\|_{L^{\infty}\left(B_{T}\right)} \leq \frac{C}{h_{T}^{d / 2}}\left\|q_{T}\right\|_{L^{2}\left(B_{T}^{i n}\right)} \tag{28}
\end{equation*}
$$

with a constant $C$ depending only on $\alpha, \beta$ and the ratio $R_{T} / r_{T}$. Thus,

$$
\left|u_{T}\right|_{H^{1}(T)} \leq|T|^{1 / 2}\left|u_{T}\right|_{W^{1, \infty}\left(B_{T}\right)} \leq C h_{T}\left\|q_{T}\right\|_{L^{2}(T)}
$$

which proves the estimate in $H^{1}(T)$ norm in 27 . Similarly, $\left\|u_{T}\right\|_{L^{2}(T)} \leq C h_{T}^{2}\left\|q_{T}\right\|_{L^{2}(T)}$ and the estimate in $L^{2}(\partial T)$ norm in 27 follows by the trace inverse inequality.

It remains to prove (26) in the case of operator $\mathscr{L}$ with variable coefficients. To this end, we use the estimates in (28) as follows

$$
\begin{aligned}
\int_{T} q_{T} \mathscr{L} u_{T} & =\int_{T} q_{T} \mathscr{L}^{0} u_{T}+\int_{T} q_{T} \partial_{i}\left(\left(A_{i j}-A_{i j}^{0}\right) \partial_{j} u_{T}\right) \\
& \geq\left\|q_{T}\right\|_{L^{2}(T)}^{2}-\left\|q_{T}\right\|_{L^{2}(T)}|T|^{1 / 2}\left[\max _{x \in T}\left|A(x)-A_{0}\right|\left|u_{T}\right|_{W^{2, \infty}(T)}+\max _{x \in T}\left|\nabla A(x) \| u_{T}\right|_{W^{1, \infty}(T)}\right] \\
& \geq\left\|q_{T}\right\|_{L^{2}(T)}^{2}-\left\|q_{T}\right\|_{L^{2}(T)}|T|^{1 / 2} h_{T} \max _{x \in T}|\nabla A(x)| \frac{C}{h_{T}^{d / 2}}\left\|q_{T}\right\|_{L^{2}\left(B_{T}^{i n}\right)} \\
& \geq\left\|q_{T}\right\|_{L^{2}(T)}^{2}-C h_{T}\left\|q_{T}\right\|_{L^{2}(T)}^{2} \geq \frac{1}{2}\left\|q_{T}\right\|_{L^{2}(T)}
\end{aligned}
$$

for sufficiently small $h_{T}$.
Corollary 1 Introduce the bilinear form

$$
b_{h}(q, v)=\sum_{T \in \mathscr{T}_{h}} h_{T}^{2} \int_{T} q \mathscr{L} u
$$

and the space

$$
M_{h}=\left\{v \in L^{2}(\Omega):\left.v\right|_{T} \in \mathbb{P}_{k-2}(T), \forall T \in \mathscr{T}_{h}\right\}
$$

Equip the space $V_{h}$ with the triple norm (25) and the space $M_{h}$ with

$$
\|q\|_{h}=\left(\sum_{T \in \mathscr{T}_{h}} h_{T}^{2}\|q\|_{L^{2}(T)}^{2}\right)^{1 / 2}
$$

The bilinear form $b_{h}$ satisfies the inf-sup condition

$$
\begin{equation*}
\inf _{q_{h} \in M_{h}} \sup _{v_{h} \in V_{h}} \frac{b_{h}\left(q_{h}, v_{h}\right)}{\left\|q_{h}\right\|_{h}\| \| v_{h} \|} \geq \delta \tag{29}
\end{equation*}
$$

with a mesh-independent constant $\delta>0$. Moreover, $b_{h}$ is continuous on $M_{h} \times V_{h}$ with a mesh-independent continuity bound.

Proof Take any $q_{h} \in M_{h}$, denote $q_{T}=\left.q_{h}\right|_{T}$, construct $u_{T}$ as in Lemma 2 and introduce $u_{h} \in V_{h}$ by $\left.u_{h}\right|_{T}=u_{T}$ on all $T \in \mathscr{T}_{h}$. This yields using 26) and 27,

$$
\frac{b_{h}\left(q_{h}, u_{h}\right)}{\left\|u_{h}\right\|} \geq \frac{\sum_{T \in \mathscr{T}_{h}} \frac{h_{T}^{2}}{2}\left\|q_{h}\right\|_{L^{2}(T)}^{2}}{\left(\sum_{T \in \mathscr{F}_{h}} C h_{T}^{2}\left\|q_{h}\right\|_{L^{2}(T)}^{2}\right)^{1 / 2}}=\frac{2}{\sqrt{C}}\left\|q_{h}\right\|_{h}
$$

which is equivalent to 29 with $\delta=2 / \sqrt{C}$. Finally, the continuity of $b_{h}$ is easily seen from the inverse inequality 22 .

Lemma 2 implies that operator $\pi_{T, k-2} \mathscr{L}$ appearing in (14) is surjective from $\mathbb{P}^{k}(T)$ to $\mathbb{P}^{k=2}(T)$ so that 14 has indeed a solution at least on sufficiently refined meshes. The existence of a solution to (17) follows from the coercivity of $a_{h}$. Thus, scheme (14)-(18) produces some $u_{h} \in V_{h}$. In order to establish the error estimates for this $u_{h}$, we reinterpret its definition as a saddle point problem.

Lemma 3 The problem of finding $u_{h} \in V_{h}$ and $p_{h} \in M_{h}$ such that

$$
\begin{align*}
a_{h}\left(u_{h}, v_{h}\right)+b_{h}\left(p_{h}, v_{h}\right) & =L_{h}\left(v_{h}\right), & & \forall v_{h} \in V_{h}  \tag{30}\\
b_{h}\left(q_{h}, u_{h}\right) & =\sum_{T \in \mathscr{T}_{h}} h_{T}^{2} \int_{T} f q_{h}, & & \forall q_{h} \in M_{h} \tag{31}
\end{align*}
$$

has a unique solution. Moreover, $u_{h}$ given by (30)-(37) coincides with $u_{h}$ given by (14)-(18). ${ }^{3}$ This implies that $u_{h}$ produced by the scheme (14)-(18) is unique.

Proof The existence and uniqueness of the solution to 30 - 31 follows from the standard theory of saddle point problems, cf. for example Corollary 4.1 from [16], thanks to the coercivity of $a_{h}$ (Lemma 1) and to the inf-sup property on $b_{h}$ (Corollary 1.

In order to explore its relation with $u_{h}=u_{h}^{l o c}+u_{h}^{\prime}$ from $14-18$, we note $b_{h}\left(q_{h}, u_{h}^{l o c}\right)=$ $\sum_{T \in \mathscr{T}_{h}} h_{T}^{2} \int_{T} f q_{h}$ for all $q_{h} \in M_{h}$ and $b_{h}\left(q_{h}, u_{h}^{\prime}\right)=0$ for all $q_{h} \in \bar{M}_{h}$ since $u_{h}^{\prime} \in V_{h}^{\prime}$. We obtain thus

$$
\begin{equation*}
b_{h}\left(q_{h}, u_{h}^{l o c}+u_{h}^{\prime}\right)=\sum_{T \in \mathscr{T}_{h}} h_{T}^{2} \int_{T} f q_{h}, \quad \forall q_{h} \in M_{h} \tag{32}
\end{equation*}
$$

Eq. (17) can be rewritten as

$$
L_{h}\left(v_{h}^{\prime}\right)-a_{h}\left(u_{h}^{l o c}+u_{h}^{\prime}, v_{h}^{\prime}\right)=0, \quad \forall v_{h}^{\prime} \in V_{h}^{\prime}
$$

[^3]This, together with the fact that $V_{h}^{\prime}$ is precisely the kernel of the bilinear form $b_{h}$, i.e. $V_{h}^{\prime}=\left\{v_{h} \in V_{h}: b\left(q_{h}, v_{h}\right)=0, \forall q_{h} \in M_{h}\right\}$, means that there exists $\tilde{p}_{h} \in M_{h}$ such that

$$
b_{h}\left(\tilde{p}_{h}, v_{h}\right)=L_{h}\left(v_{h}\right)-a_{h}\left(u_{h}^{l o c}+u_{h}^{\prime}, v_{h}\right), \quad \forall v_{h} \in V_{h},
$$

cf. Lemma 4.1 from [16]. The last equation can be rewritten as

$$
\begin{equation*}
a_{h}\left(u_{h}^{l o c}+u_{h}^{\prime}, v_{h}\right)+b_{h}\left(\tilde{p}_{h}, v_{h}\right)=L_{h}\left(v_{h}\right), \quad \forall v_{h} \in V_{h}, \tag{33}
\end{equation*}
$$

Comparing (33)-(32) on one hand with (30)-(31) on the other hand, we identify $u_{h}$ with $u_{h}^{l o c}+u_{h}^{\prime}$ and $p_{h}$ with $\tilde{p}_{h}$.

Theorem 2 Assume that the solution $u$ to $\sqrt{1})$ is in $H^{k+1}(\Omega)$. Under the assumptions of Lemma 1 and $h$ sufficiently small, the scSIP method (14)-(18) produces the unique solution $u_{h} \in V_{h}$, which satisfies

$$
\begin{equation*}
\left|u-u_{h}\right|_{H^{1}(\mathscr{T h})} \leq C h^{k}|u|_{H^{k+1}(\Omega)} \tag{34}
\end{equation*}
$$

If, moreover, the elliptic regularity property holds for (17), then

$$
\begin{equation*}
\left\|u-u_{h}\right\|_{L^{2}(\Omega)} \leq C|u|_{H^{k+1}(\Omega)} h^{k+1} \tag{35}
\end{equation*}
$$

Proof We shall use the saddle point reformulation (30)-(31). This discretization is consistent. Indeed setting $p=0$ we have

$$
\begin{aligned}
a_{h}\left(u, v_{h}\right)+b_{h}\left(p, v_{h}\right) & =L_{h}\left(v_{h}\right), & \forall v_{h} \in V_{h} \\
b_{h}\left(q_{h}, u\right) & =\sum_{T \in \mathscr{T}_{h}} h_{T}^{2} \int_{T} f q_{h}, & \forall q_{h} \in M_{h}
\end{aligned}
$$

Thus, by the standard approximation theory for saddle point problems, cf. for example Proposition 2.36 from [15], recalling the coercivity of $a_{h}$ (Lemma 1] and the inf-sup property on $b_{h}$ (Corollary 1), we get

$$
\begin{aligned}
\left\|\left\|u_{h}-I_{h} u\right\|\right\|+\left\|p_{h}\right\|_{h} \leq & C \sup _{\substack{\left(v_{h}, q_{h}\right) \in V_{h} \times M_{h} \\
\left\|v_{h}\right\|\|+\| q_{h} \|_{h}=1}}\left(a_{h}\left(u_{h}-I_{h} u, v_{h}\right)+b_{h}\left(p_{h}, v_{h}\right)+b_{h}\left(q_{h}, u_{h}-I_{h} u\right)\right) \\
& =C \sup _{\substack{\left(v_{h}, q_{h}\right) \in V_{h} \times M_{h} \\
\left\|v_{h}\right\|\|+\| q_{h} \|_{h}=1}}\left(a_{h}\left(u-I_{h} u, v_{h}\right)+b_{h}\left(q_{h}, u-I_{h} u\right)\right) \\
& \leq C\left(\left\|u-I_{h} u\right\|_{a}^{2}+\sum_{T \in \mathscr{T}_{h}} h_{T}^{2}\left\|\mathscr{L}\left(u-I_{h} u\right)\right\|_{L^{2}(T)}^{2}\right)^{\frac{1}{2}}
\end{aligned}
$$

with the augmented triple norm $\mid\|\cdot\| \|_{a}$ defined by

$$
\|v\|_{a}^{2}:=\| \| v\left\|^{2}+\sum_{E \in \mathscr{E}_{h}} h_{E}\right\|\{A \nabla v \cdot n\} \|_{L^{2}(E)}^{2}
$$

Applying the interpolation estimates (20) and the triangle inequality gives

$$
\begin{equation*}
\left\|u-I_{h} u\right\|_{a}+\left\|p_{h}\right\|_{h} \leq C h^{k}|u|_{H^{k+1}} \tag{36}
\end{equation*}
$$

This implies in particular (34).
To prove the $L^{2}$ error estimate, we consider the auxiliary problem for $z \in H^{2}(\Omega)$

$$
\mathscr{L}_{z}=u-u_{h} \text { in } \Omega, \quad z=0 \text { on } \partial \Omega
$$

Then, for all $v \in H^{1}\left(\mathscr{T}_{h}\right)$ and $q \in L^{2}(\Omega)$,

$$
a_{h}(v, z)+b_{h}(q, z)=\int_{\Omega}\left(u-u_{h}\right) v+\sum_{T \in \mathscr{T}_{h}} h_{T}^{2} \int_{T}\left(u-u_{h}\right) q
$$

Setting $v=u-u_{h}$ and $q=p-p_{h}$ (with $p=0$ ) and using Galerkin orthogonality yields

$$
\begin{aligned}
\left\|u-u_{h}\right\|_{L^{2}(\Omega)}^{2}+\sum_{T \in \mathscr{T}_{h}} h_{T}^{2} \int_{T}\left(u-u_{h}\right)\left(p-p_{h}\right) & =a_{h}\left(u-u_{h}, z\right)+b_{h}\left(p-p_{h}, z\right) \\
& =a_{h}\left(u-u_{h}, z-z_{h}\right)+b_{h}\left(p-p_{h}, z-z_{h}\right)
\end{aligned}
$$

for any $z_{h} \in V_{h}$. Thus, taking $z_{h}=I_{h} z$ and applying the interpolation estimates,

$$
\begin{aligned}
&\left\|u-u_{h}\right\|_{L^{2}(\Omega)}^{2} \leq\left|a_{h}\left(u-u_{h}, z-z_{h}\right)\right|+h\left\|p-p_{h}\right\|_{h}\left(\sum_{T \in \mathscr{T}_{h}}\left\|\mathscr{L} z-\mathscr{L}_{z_{h}}\right\|_{L^{2}(T)}^{2}\right)^{1 / 2} \\
& \quad+h\left\|p-p_{h}\right\|_{h}\left\|u-u_{h}\right\|_{L^{2}(\Omega)} \\
& \leq C h\left\|u-I_{h} u\right\|_{a}|z|_{H^{2}(\Omega)}+C h\left\|p_{h}\right\|_{h}\left(|z|_{H^{2}(\Omega)}+\left\|u-u_{h}\right\|_{L^{2}(\Omega)}\right)
\end{aligned}
$$

Recalling $|z|_{H^{2}(\Omega)} \leq C\left\|u-u_{h}\right\|_{L^{2}(\Omega)}$ and (36) yields 35).

## 4 An example of assumptions on the mesh that guarantee the interpolation and inverse estimates

In this section, we adopt the following assumptions on the mesh.
M1: $\mathscr{T}_{h}$ is shape regular in the sense $(19)$ with a parameter $\rho_{1}>1$.
M2: $\mathscr{T}_{h}$ is locally quasi-uniform in the following sense: for any two mesh cells $T, T^{\prime} \in \mathscr{T}_{h}$ such that $B_{T^{\prime}} \cap B_{T} \neq \varnothing$ there holds

$$
\frac{1}{\rho_{2}} h_{T^{\prime}} \leq h_{T} \leq \rho_{2} h_{T^{\prime}}
$$

with a parameter $\rho_{2}>1$.
M3: The cell boundaries are not too wiggly: for all $T \in \mathscr{T}_{h}$

$$
|\partial T| \leq \rho_{3} h_{T}^{d-1}
$$

with a parameter $\rho_{3}>0$.

We shall show that these assumptions allow us to construct an interpolation operator $I_{h}$ to the discontinuous finite element space 10 for $k \geq 2$ and to prove the interpolation error estimate 20 and the inverse estimates $210-22$.

First of all, the assumptions that the mesh is shape regular and locally quasiuniform entail the following

Lemma 4 Define, for any $x \in \mathbb{R}^{d}$,

$$
N_{\text {ball }}(x)=\#\left\{T \in \mathscr{T}_{h}: x \in B_{T}\right\}
$$

with \# standing for the "number of". Under assumptions M1 and M2, there holds

$$
N_{\text {ball }}(x) \leq N_{\text {int }}, \quad \forall x \in \mathbb{R}^{d}
$$

with a constant $N_{\text {int }}$ depending only on $\rho_{1}$ and $\rho_{2}$.
Proof Take any $x \in \mathbb{R}^{d}$ with $N_{\text {ball }}(x)>0$ (otherwise, for $x$ with $N_{\text {ball }}(x)=0$, there is nothing to prove). We now choose arbitrarily $T^{\prime} \in \mathscr{T}_{h}$ such that $x \in B_{T^{\prime}}$, set $h_{x}=h_{T^{\prime}}$, and then consider all the mesh cells $T$ such that $x \in B_{T^{\prime}}$. By Assumption M2, $h_{T} \leq$ $\rho_{2} h_{x}$ for any such $T$. Hence, by Assumption M1, $R_{T} \leq \rho_{1} \rho_{2} h_{x}$, so that $T$ is inside the ball $B_{x}$ of radius $2 \rho_{1} \rho_{2} h_{x}$ centered at $x$. Recall that $T$ contains an inscribed ball of radius $r_{T} \geq \frac{R_{T}}{\rho_{1}} \geq \frac{h_{T}}{2 \rho_{1}} \geq \frac{h_{x}}{2 \rho_{1} \rho_{2}}$. If there are several such cells $T$, then their respective inscribed balls $B_{T}^{i n}$ do not intersect each other and they are all inside $B_{x}$. Thus, their number satisfies the bound

$$
N_{\text {ball }}(x) \leq \frac{\left|B_{x}\right|}{\min _{T \in \mathscr{T}_{h}: x \in B_{T}}\left|B_{T}^{i n}\right|} \leq \frac{\left(2 \rho_{1} \rho_{2} h_{x}\right)^{d}}{\left(\frac{h_{x}}{2 \rho_{1} \rho_{2}}\right)^{d}}=\left(2 \rho_{1} \rho_{2}\right)^{2 d}
$$

as announced.
Recall that $V_{h}$ is the discontinuous FE space on $\mathscr{T}_{h}$ of degree $k \geq 2$, cf. (10).
Lemma 5 (Local interpolation estimate) Take any $T \in \mathscr{T}_{h}$. Let $\pi_{h}$ denote the $L^{2}\left(B_{T}\right)$ orthogonal projection to the space of polynomials, i.e. given $v \in L^{2}\left(B_{T}\right), v_{h}=\pi_{h} v$ is a polynomial of degree $\leq k$ such that

$$
\int_{B_{T}} v_{h} \varphi_{h}=\int_{B_{T}} v \varphi_{h} \quad \forall \varphi_{h} \in \mathbb{P}^{k}(T)
$$

Under Assumptions M1 and M3, we have then for any $v \in H^{k+1}\left(B_{T}\right)$

$$
\begin{aligned}
\left|v-v_{h}\right|_{H^{1}(T)} & +\frac{1}{h_{T}}\left\|v-v_{h}\right\|_{L^{2}(T)}+h_{T}\left|v-v_{h}\right|_{H^{2}(T)} \\
& +\sqrt{h_{T}}\left\|\nabla\left(v-v_{h}\right)\right\|_{L^{2}(\partial T)}+\frac{1}{\sqrt{h_{T}}}\left\|v-v_{h}\right\|_{L^{2}(\partial T)} \leq C h_{T}^{k}|v|_{H^{k+1}\left(B_{T}\right)}
\end{aligned}
$$

with a constant $C>0$ depending only on $\rho_{1}$ and $\rho_{3}$.

Proof Since $H^{k+1}\left(B_{T}\right)$ is embedded into $L^{\infty}\left(B_{T}\right)$, Deny-Lions lemma together with a scaling argument (cf. Theorem 15.3 from [7]) entail

$$
\left\|v-v_{h}\right\|_{L^{\infty}\left(B_{T}\right)} \leq C h_{T}^{k+1-d / 2}|v|_{H^{k+1}\left(B_{T}\right)}
$$

Hence,

$$
\left\|v-v_{h}\right\|_{L^{2}(T)} \leq|T|^{\frac{1}{2}}\left\|v-v_{h}\right\|_{L^{\infty}\left(B_{T}\right)} \leq C h_{T}^{k+1}|v|_{H^{k+1}\left(B_{T}\right)}
$$

and, in view of the hypothesis $|\partial T| \leq \rho_{3} h_{T}^{d-1}$,

$$
\left\|v-v_{h}\right\|_{L^{2}(\partial T)} \leq\left(\rho_{3} h_{T}^{d-1}\right)^{\frac{1}{2}}\left\|v-v_{h}\right\|_{L^{\infty}\left(B_{T}\right)} \leq C h_{T}^{k+1 / 2}|v|_{H^{k+1}\left(B_{T}\right)}
$$

The estimates for $\left|v-v_{h}\right|_{H^{1}(T)}$ and $\left\|\nabla v-\nabla v_{h}\right\|_{L^{2}(\partial T)}$ are proven in the same way starting from

$$
\left\|\nabla v-\nabla v_{h}\right\|_{L^{\infty}\left(B_{T}\right)} \leq C h_{T}^{k-d / 2}|v|_{H^{k+1}\left(B_{T}\right)}
$$

This is valid since $H^{k+1}\left(B_{T}\right)$ is embedded into $W^{1, \infty}\left(B_{T}\right)$ for $k \geq 2$.
Finally, the estimate for $\left|v-v_{h}\right|_{H^{2}(T)}$ holds thanks to the embedding of $H^{k+1}\left(B_{T}\right)$ into $H^{2}\left(B_{T}\right)(k \geq 1)$.

Lemma 6 (Global interpolation estimate) Let $I_{h}: H^{k+1}(\Omega) \rightarrow V_{h}$ denote the operator obtained by first extending a function $v \in H^{k+1}(\Omega)$ by a function $\tilde{v} \in H^{k+1}\left(\mathbb{R}^{d}\right)$ and then applying the local operator $\pi_{h}$ from Lemma 5 to $\tilde{v}$ on every $T \in \mathscr{T}_{h}$, i.e. $\left.I_{h} v\right|_{T}:=\left.\left(\pi_{h} \tilde{v}\right)\right|_{T}$ on any $T \in \mathscr{T}_{h}$. Then, under Assumptions M1-M3, 20) holds for any $v \in H^{k+1}(\Omega)$

Proof First, extension theorem for Sobolev spaces [1] insure that there exists $\tilde{v} \in$ $H^{k+1}\left(\mathbb{R}^{d}\right)$ such that

$$
\left.\tilde{v}=v \text { on } \Omega \quad \text { and } \quad\|\tilde{v}\|_{H^{k+1}\left(\mathbb{R}^{d}\right)} \leq C\|\tilde{v}\|_{H^{k+1}(\Omega}\right)
$$

To prove (20), we sum the local interpolation estimates of Lemma 5 over all the mesh cells and then use Assumption M2 and Lemma 4

$$
\begin{gathered}
\sum_{T \in \mathscr{T}}\left(\left|v-v_{h}\right|_{H^{1}(T)}^{2}+\frac{1}{h_{T}^{2}}\left\|v-v_{h}\right\|_{L^{2}(T)}^{2}+h_{T}^{2}\left|v-v_{h}\right|_{H^{2}(T)}^{2}+h_{T}\left\|\nabla v-\nabla v_{h}\right\|_{L^{2}(\partial T)}^{2}+\frac{1}{h_{T}}\left\|v-v_{h}\right\|_{L^{2}(\partial T)}^{2}\right) \\
\leq C \sum_{T \in \mathscr{T}_{h}} h_{T}^{2 k} \int_{B_{T}}\left|\nabla^{k+1} v\right|^{2} d x \leq C \int_{\Omega}\left(\max _{T \in \mathscr{T}_{h}: x \in B_{T}} h_{T}\right)^{2 k} N_{\text {ball }}(x)\left|\nabla^{k+1} v\right|^{2} d x \\
\leq C N_{\text {int }} \rho_{2}^{2 k} \sum_{T^{\prime} \in \mathscr{T}_{h}} h_{T^{\prime}}^{2 k}|v|_{H^{k+1}(T)}^{2}
\end{gathered}
$$

Lemma 7 (Inverse inequalities) Under assumptions M1 and M3, (21) and (22) hold for any $v_{h} \in V_{h}$ and any $T \in \mathscr{T}_{h}$.

Proof Both bounds in 21 follow immediately from the following one: for any polynomial $q_{h}$ of degree $\leq l$ one has

$$
\left\|q_{h}\right\|_{L^{\infty}(T)} \leq \frac{C}{h_{T}^{d / 2}}\left\|q_{h}\right\|_{L^{2}(T)}
$$

with $C>0$ depending only on $\rho_{1}$ and $l$. This follows in turn from

$$
\left\|q_{h}\right\|_{L^{\infty}\left(B_{T}\right)} \leq \frac{C}{h_{T}^{d / 2}}\left\|q_{h}\right\|_{L^{2}\left(B_{T}^{i n}\right)}
$$

where $B_{T}^{i n}$ is the largest ball inscribed in $T$. Scaling the ball $B_{T}$ to a ball of radius 1 $B_{1}$ and considering all the possible positions of the inscribed ball, the last inequality can be rewritten as

$$
\left\|q_{h}\right\|_{L^{\infty}\left(B_{1}\right)} \leq C \min _{B^{i n} \subset B_{1}, B^{i n} \text { a ball of radius } \geq \rho_{1}^{-1}}\left\|q_{h}\right\|_{L^{2}\left(B_{T}^{i n}\right)}
$$

This is valid for any polynomial of degree $l$ by equivalence of norms.
The remaining inverse inequality (22) can be proven similarly:

$$
\left|v_{h}\right|_{H^{2}(T)} \leq C h_{T}^{d / 2}\left|v_{h}\right|_{W^{2, \infty}\left(B_{T}\right)} \leq C h_{T}^{d / 2-1}\left|v_{h}\right|_{W^{1, \infty}\left(B_{T}\right)} \leq \frac{C}{h_{T}}\left|v_{h}\right|_{H^{1}\left(B_{T}^{i n}\right)} \leq \frac{C}{h_{T}}\left|v_{h}\right|_{H^{1}(T)}
$$

## 5 Implementation and numerical results

We shall illustrate the convergence of SIP and scSIP methods on polygonal meshes obtained by agglomerating the cells of a background triangular mesh. Both the mesh construction and the following calculations are done in FreeFEM ++ [18]. An example of such a mesh is given in Fig. 1. To construct it, we take a positive integer $n(n=4$ in the Figure), let FreeFEM++ to construct a Delaunay triangulation of $\Omega=(0,1)^{2}$ with $4 n$ boundary nodes on each side of the square, and finally agglomerate the triangles of this mesh into $n \times n$ cells as follows. We start by attributing the triangle containing the point

$$
\begin{equation*}
O_{i+j n}=\left(\frac{i-1 / 2}{n}, \frac{j-1 / 2}{n}\right), \quad i, j=1, \ldots, n \tag{37}
\end{equation*}
$$

to the cell number $i+j n$. Then, iteratively, we run over all the cells and attach yet unattributed triangles neighboring a triangle from a cell to the same cell, until all the triangles are attributed.

Some details of our implementations are given below, followed by the numerical results on two test cases.

Fig. 1 On the left, a polygonal mesh consisting of $4 \times 4$ cells, which are obtained by the agglomeration of the triangles of a finer mesh seen on the right.

### 5.1 Implementation of SIP ans scSIP methods

Let us enumerate the mesh cells as $\left\{T_{1}, \ldots, T_{N_{e}}\right\}$ and introduce a basis $\left\{\phi_{i}^{(l)}\right\}_{i=1, \ldots, N_{k}}$ of $\mathbb{P}_{k}\left(T_{l}\right)$ on every cell $T_{l}$. Here and below, $N_{e}$ is the number of cells in $\mathscr{T}_{h}$ and $N_{k}$ denotes the dimension of $\mathbb{P}_{k}$. In our implementation, we form the basis out of monomials shifted to the "center" $O_{l}=\left(O_{l, x}, O_{l, y}\right)$ of the cell $T_{l}$, cf. 37. i.e.

$$
\phi_{i}^{(l)}(x, y)=\phi_{i_{1} i_{2}}^{(l)}(x, y)=\left(x-O_{l, x}\right)^{i_{1}}\left(y-O_{l, y}\right)^{i_{2}}
$$

regrouping the multi-indexes $\left(i_{1}, i_{2}\right), 0 \leq i_{1} \leq k, 0 \leq i_{2} \leq k-i_{1}$ into a single index $i$ ranging from 1 to $N_{k}$. We form then the matrices $\mathbf{A}^{(l m)}$ for every pair of cells $T_{l}$ and $T_{m}$ sharing some parts of their boundaries. These matrices of size $N_{k} \times N_{k}$ represent the bilinear form $a_{h}$ in our bases and have the following entries

$$
A_{i j}^{(l m)}=a_{h}\left(\phi_{i}^{(l)}, \phi_{j}^{(m)}\right)
$$

We also compute the right-hand side vectors $\vec{F}^{(l)} \in \mathbb{R}^{N_{k}}$ with $F_{i}^{(l)}=L_{h}\left(\phi_{i}^{(l)}\right)$ on every cell $T_{l}$, put all $\vec{F}^{(l)}$ into a single vector $\vec{F}$ of size $N_{D O F}=N_{e} N_{k}$, put the matrices $\mathbf{A}^{(l m)}$ into the block matrix A of size $N_{D O F} \times N_{D O F}$, and finally find $\vec{U} \in \mathbb{R}^{N_{D O F}}$ as solution to

$$
\mathbf{A} \vec{U}=\vec{F}
$$

The vector $\vec{U}$ represents the numerical solution by the SIP method 11 in the following sense: decomposing $\vec{U}$ into the cell-by-cell components $\vec{U}^{(l)}=\left\{U_{i}^{(l)}\right\} \in \mathbb{R}^{N_{k}}, u_{h}$ in 11 is given on each cell $T_{l}$ by $u_{h}=\sum_{i=1}^{N_{k}} U_{i}^{(l)} \phi_{i}^{(l)}$.

Turning to the scSIP method, we introduce moreover a basis of $\mathbb{P}_{k-2}\left(T_{l}\right),\left\{\psi_{i}^{(l)}\right\}_{i=1, \ldots, N_{k-2}}$, and form the matrices $\mathbf{B}^{(l)}$ of size $N_{k-2} \times N_{k}$ on every cell $T_{l}$ with the entries

$$
B_{i j}^{(l)}=\int_{T_{l}} \psi_{i}^{(l)} \mathscr{L} \phi_{j}^{(l)}=\int_{T_{l}} \psi_{i}^{(l)} \cdot A \nabla \phi_{j}^{(l)}-\int_{\partial T_{l}} \psi_{i}^{(l)} n \cdot A \nabla \phi_{j}^{(l)}
$$

These matrices will serve to compute the local contributions in (14) as well as to construct a basis of the space $V_{h}^{\prime}$ in 15). As mentioned earlier, the solution to 14 is not unique and one can propose several ways to compute a solution in practice. In our implementation, we have opted for a solution to solving the following saddle-point problem on every cell $T_{l}$

$$
\begin{align*}
\vec{u}^{(l)}+\left(\mathbf{B}^{(l)}\right)^{T} \vec{p}^{(l)} & =0 \\
\mathbf{B}^{(l)} \vec{u}^{(l)} & =\vec{F}_{\psi}^{(l)} \tag{38}
\end{align*}
$$

with $\vec{F}_{\psi}^{(l)}=\left\{F_{\psi, i}^{(l)}\right\} \in \mathbb{R}^{N_{k-2}}, F_{\psi, i}^{(l)}=\int_{T_{l}} f \psi_{i}^{(l)}$. The unknowns here are $\vec{u}^{(l)} \in \mathbb{R}^{N_{k}}$ and $\vec{p}^{(l)} \in \mathbb{R}^{N_{k-2}}$ with $\vec{u}^{(l)}$ representing $u_{h}^{l o c}$ on $T_{l}$ in the basis $\left\{\phi_{i}^{(l)}\right\}$. The saddle-point problem above is well posed thanks to Lemma 2

A basis for $V_{h}^{\prime}$ from 15 - 16 can be constructed on every cell $T_{l}$ using a saddlepoint problem similar to 38 . Indeed, $V_{h}^{\prime}$ on $T_{l}$ is the kernel of $\mathbf{B}^{(l)}$. It is thus given by the span of vectors $\left\{\vec{u}^{(l, 1)}, \ldots, \vec{u}^{\left(l, N_{k}\right)}\right\} \subset \mathbb{R}^{N_{k}}$ with $\vec{u}^{(l, s)}$ defined by

$$
\begin{align*}
\vec{u}^{(l, s)}+\left(\mathbf{B}^{(l)}\right)^{T} \vec{p}^{(l, s)} & =\vec{e}^{(s)} \\
\mathbf{B}^{(l)} \vec{u}^{(l, s)} & =0 \tag{39}
\end{align*}
$$

where $\left\{\vec{e}^{(1)}, \ldots, \vec{e}^{\left(N_{k}\right)}\right\}$ is the canonical basis of $\mathbb{R}^{N_{k}}$. In practice, we solve the problem above successively for $s=1,2, \ldots$ and apply the Gram-Schmidt procedure to ortho-normalize the vectors $\vec{u}^{(l, s)}$ getting rid of the vectors which turn out to be linearly dependent from the preceding ones. This provides us with a basis for $\left.V_{h}^{\prime}\right|_{T_{l}}$ consisting of $N_{k}^{\prime}=N_{k}-N_{k-2}$ vectors (actually, the Gram-Schmidt process can be stopped once $N_{k}^{\prime}$ ortho-normal vectors have been found).

Remark 1 In the case when the coefficient matrix $A$ is constant (and thus does not change from one mesh cell to another), the restriction on the functions in $V_{h}^{\prime}$, i.e. $\int_{T} q_{h} \mathscr{L} v_{h}^{\prime}=0$ for all $q_{h} \in \mathbb{P}_{k-2}(T)$, implies in fact $\mathscr{L} v_{h}^{\prime}=0$ on every cell $T$. This is independent from the shape of $T$ so that the structure of $V_{h}^{\prime}$ is the same on all the cells, and one can keep the same basis for $V_{h}^{\prime}$ everywhere.

For example, in the case of Poisson equation $(\mathscr{L}=-\Delta)$ in 2D, $v_{h}$ supported on a cell $T$ is in $V_{h}^{\prime}$ if and only if $\Delta v_{h}=0$. Expanding $v_{h}$ in the basis of monomials $v_{h}=\sum_{i_{1}, i_{2}} v_{i_{1} i_{2}} \phi_{i_{1} i_{2}}^{(l)}$ this gives rise to the equations

$$
\left(i_{1}+2\right)\left(i_{1}+1\right) v_{i_{1}+2, i_{2}}+\left(i_{2}+2\right)\left(i_{2}+1\right) v_{i_{1}, i_{2}+2}=0
$$

for all non-negative $\left(i_{1}, i_{2}\right)$. These equations can be easily solved to provide a basis for $V_{h}^{\prime}$ on all the cells.

In our implementation, to keep things simple and the code suitable for both cases of either constant $A$ or varying $A$, we have used another strategy: if $A$ is constant, we perform the Gram-Schmidt ortho-normalization on the solutions to 39 on the mesh cell number 1 only. We keep then the same basis (as expressed by the expansion coefficients in $\left\{\phi_{i}^{(l)}\right\}_{i=1, \ldots, N_{k}}$ ) on all the other cells $T_{l}, l \geq 2$.

Fig. 2 The test case with Poisson equation: the error in $L^{2}$ norm and $H^{1}$ semi-norm vs. mesh-size $h$. The solid lines with squares represent the SIP method. The dashed lines with circles represent the scSIP method.

Having constructed the basis for $V_{h}^{\prime}$, it remains to solve the global problem 17). We introduce to this end on every cell $T_{l}$ the matrices $\mathbf{M}^{(l)}$ of size $N_{k} \times N_{k}^{\prime}$ putting together the vectors representing the basis for $V_{h}^{\prime}$ on $T_{l}$. We form then the reduced matrices $\mathbf{A}^{\prime(l m)}$ of size $N_{k}^{\prime} \times N_{k}^{\prime}$ and the reduced right-hand side vectors $\vec{F}^{\prime(l)}$ out of full $\mathbf{A}^{(l m)}$ and $\vec{F}^{(l)}$ (already introduced in the description of the SIP method implementation) by, cf. 17,

$$
\mathbf{A}^{\prime(l m)}=\left(\mathbf{M}^{(l)}\right)^{T} \mathbf{A}^{(l m)} \mathbf{M}^{(m)} \text { and } \vec{F}^{\prime(l)}=\left(\mathbf{M}^{(l)}\right)^{T}\left(\vec{F}^{(l)}-\sum_{m} \mathbf{A}^{(l m)} \vec{u}^{(m)}\right)
$$

with $\vec{u}^{(m)}$ representing $u_{h}^{l o c}$ on $T_{m}$ and computed by 38 . Putting the matrices $\mathbf{A}^{(l m)}$ into the block matrix $\mathbf{A}^{\prime}$ of size $N_{D O F}^{\prime} \times N_{D O F}^{\prime}$ with $\bar{N}_{D O F}=N_{e} N_{k}^{\prime}$ and the vectors $\vec{F}^{\prime}(l)$ into a single vector $\vec{F}^{\prime}$, we compute $\vec{U}^{\prime} \in \mathbb{R}^{N_{D O F}^{\prime}}$ as solution to

$$
\mathbf{A}^{\prime} \vec{U}^{\prime}=\vec{F}^{\prime}
$$

The vector $\vec{U}^{\prime}$ represents the solution to 17 . The solution $u_{h}$ by the scSIP method is finally reconstructed as follows: decomposing $\vec{U}^{\prime}$ into the cell-by-cell components $\vec{U}^{\prime(l)}=\left\{U_{i}^{\prime(l)}\right\} \in \mathbb{R}^{N_{k}^{\prime}}$, we recall $\vec{u}^{(l)}$ computed on each cell $T_{l}$ by 38, introduce $\overrightarrow{\widetilde{U}}^{(l)}=\left\{\widetilde{U}_{i}^{(l)}\right\} \in \mathbb{R}^{N_{k}}$ as $\overrightarrow{\widetilde{U}}^{(l)}=\vec{u}^{(l)}+\mathbf{M}^{(l)} \vec{U}^{\prime(l)}$, and set $u_{h}$ on $T_{l}$ as $u_{h}=$ $\sum_{i=1}^{N_{k}} \widetilde{U}_{i}^{(l)} \phi_{i}^{(l)}$.

### 5.2 The first test case: Poisson equation

We have considered the Poisson equation, i.e. (1) with $A=I$, on $\Omega=(0,1)^{2}$ with homogeneous Dirichlet boundary conditions $g=0$ and the exact solution $u=\sin (\pi x) \sin (\pi y)$. We have applied SIP method (11) and scSIP method (14)-(17) to this problem on the agglomerated meshes as described in the preamble of this Section. The results are

Fig. 3 Test case with the non constant coefficient matrix $A$ : the error in $L^{2}$ norm and $H^{1}$ semi-norm vs. mesh-size $h$. The solid lines with squares represent the SIP method. The dashed lines with circles represent the scSIP method.
presented in Fig. 2. In a slight deviation from the general notations, we set here the mesh-size as $h=1 / n$ on the $n \times n$ mesh, and $h_{E}=h$ on all the edges in 12). Three choices for the polynomial space degree $k$ were investigated, namely $k=2,3,4$ and the penalty parameter $\gamma$ in 12 was set to $2 k(k+1)$ (by a loose extrapolation to the polygonal meshes of the bound on the constant in the inverse inequality on a triangle in [23]). The numerical results confirm the theoretically expected order of convergence in both $L^{2}$ norm and $H^{1}$ semi-norm. They also demonstrate that the approximation produced by SIP and scSIP methods are very close to each other.
5.3 The second test case: non-constant coefficients $A$

We now consider problem (1) with a non-constant coefficient matrix

$$
A=\left(\begin{array}{cc}
1+x & x y \\
x y & 1+y
\end{array}\right)
$$

set again on $\Omega=(0,1)^{2}$. The right-hand side $f$ and non-homogeneous Dirichlet boundary conditions $g$ are chosen so that the exact solution is given by $u=e^{x y}$. The results are presented in Fig. 3 using the same meshes and parameters $h, h_{E}$, and $\gamma$ as in the first test case. We arrive at the same conclusions about the convergence of SIP and scSIP methods as before.

Acknowledgements I am grateful to Simon Lemaire for interesting discussions about HHO and msHHO methods, which were the starting point of conceiving the present article.

[^1]:    ${ }^{1}$ The usual SIP DG method makes perfect sense also for piecewise linear polynomials $(k=1)$. We restrict ourselves however to $k \geq 2$ since the forthcoming modification of the method allowing for the static condensation is pertinent to this case only.

[^2]:    ${ }^{2}$ The usual choice $h_{E}=\operatorname{diam}(E)$ is not appropriate on general meshes since some of the facets can be of much smaller diameter than that of the adjacent cell.

[^3]:    ${ }^{3}$ More precisely, all solutions $u_{h}$ of $14-18$ may be accompanied by $p_{h} \in M_{h}$ so that the resulting couples $\left(u_{h}, p_{h}\right)$ also solve $30-31$. Since the solution to $30-31$ is unique, the inverse statement is also true: $u_{h}$ given by $30-31$ is also a solution to $\sqrt{14}-18$.
